209 prefabs

Living water

A real character

Drag-and-drop props,
ready to build with.

Ripples, floats,
splashes and warps.

Weighty movement,
ladders, crates,
swimming. Before you
start

If everything looks pink after importing, your project is not using URP yet.

Go to **Edit** → **Project Settings** → **Graphics** and drag in `Settings/UniversalRP.asset` from the pack folder. That is the single most common setup issue, and it takes ten seconds to fix.

What is inside

Content	Amount
Ready-to-drag prefabs	209 total — 171 new in this Extended pack, plus the 32 from the original pack
Sprites	236 hand-drawn PNGs, sorted into foreground, background and platform sets
Demo level	1 fully playable scene, roughly 1,350 units wide
Effects	Dust, falling leaves, drifting smoke, water splash
Systems	Character controller, follow camera, interactive water, pushable crates, post-processing

Quick start

1. Import the pack into your project.
2. Open `Assets/Dark 2D World - Extended/Demo Scenes/DEMO.unity`
3. Press **Play**.
4. Walk right and explore. Everything you see is built from prefabs you can drag into your own scenes.
5. When you want to build your own level, jump to **Building your own level** below.

The demo scene is the best documentation there is. Pause the game, click things in the Hierarchy, and see how they are put together. Nothing in it is hidden or locked.

Controls

Key	What it does
A / D or Left / Right	Walk. The character builds up speed rather than snapping to it, which is what gives it weight.
Space	Jump. Hold it for a full jump, tap it for a small hop.
W / S or Up / Down	Climb, while standing on a ladder.
Space on a ladder	Jump off. Hold left or right at the same time to leap sideways.
E (hold)	Grab a crate, then walk to push or pull it. Bigger crates are heavier and slow you down more.
Space in water	Swim upwards. Near the surface it becomes a proper jump so you can climb out.

All of these keys can be changed in the Inspector — see **The character** below.

Where everything lives

Folder	What is in it
Demo Scenes	The playable demo level.
Prefabs/Extended Prefabs	The 171 new props — trees, huts, cliffs, bridges, lanterns, chains, platforms, and the Interactive Water prefab.
Prefabs/Base Prefabs	The 32 props carried over from the original free pack.
Prefabs/Particles	Dust motes, falling leaves, drifting smoke, water splash.
Prefabs/Player & Systems	The character and the camera. Drag both into any scene to get moving.
Sprites	All the raw artwork, if you would rather place sprites by hand.
Scripts	Five short scripts, grouped by what they do: Camera, Player, Water.
Shaders	The water shader and the underwater distortion shader.

Folder	What is in it
Settings	URP settings, the 2D renderer, and the post-processing profile.

Building your own level

The demo level open in the Unity Scene view — everything is made of ordinary prefabs you can move, duplicate and delete

1. Create a new scene, or duplicate the demo scene and delete the level art.
2. Drag **Player** and **Main Camera** from **Prefabs/Player & Systems** into the scene. The camera finds the character on its own.
3. Drag ground and platform prefabs from **Prefabs/Extended Prefabs** into the scene and arrange them.
4. Press **Play** and walk around.

The four layers that matter

The pack uses Unity Layers to tell things apart. If something behaves oddly, this table is almost always the answer.

Layer	Put this on it
Player	The character. Keeping it off Default is what stops it detecting itself as ground.
Pushable	Crates, logs, the boat — anything the character can shove.
Water	The water volume.
Default	Everything else: ground, walls, scenery.

There are also two **Tags** in use: **Player** on the character, and **Ladder** on any ladder you want to be climbable.

The character

Select the **Player** object and look at the Inspector. Settings are grouped into sections, every one has a tooltip if you hover over it, and you can safely change any of them while the game is running to find a feel you like.

While the game is playing, the Inspector shows a **Live State** box — whether the character is grounded, on a ladder, in water, or pushing something. It is the quickest way to work out why something is not behaving.
The Inspector will also warn you, in plain English, if something is set up wrong.

Movement

Setting	In plain words
Moving Speed	How fast the character walks at full pelt.
Ground Acceleration	How quickly it gets up to that speed. Lower feels heavier and more deliberate.
Ground Deceleration	How quickly it stops. Lower makes it slide a little, which reads as weight.
Air Acceleration / Deceleration	The same two things, but while jumping. Keep them lower than the ground values so jumps commit.

Jump

Setting	In plain words
Jump Force	How high it jumps. Note this is pushed against the character's weight, so a heavier Rigidbody jumps lower.
Fall Gravity Multiplier	Extra gravity on the way down. This is the single setting that stops a jump feeling floaty. Raise it for a snappier game.
Low Jump Multiplier	How quickly a jump is cut short when you let go of the button early. Higher gives you finer control over small hops.
Coyote Time	A tiny grace period after walking off a ledge where a jump still counts. It hides the moment where players swear they pressed jump in time.
Jump Buffer Time	The same forgiveness at the other end — a jump pressed just before landing still fires.
Max Fall Speed	A speed limit for falling, so long drops stay readable.

Ladders

Setting	In plain words
Climb Speed	How fast the character goes up and down.
Ladder Jump Scale	How much of a normal jump you get when jumping off a ladder.
Ladder Jump Push	How far sideways you leap when holding a direction as you jump off. Set it to  if you want ladder jumps to go straight up.
Ladder Regrab Delay	A short pause before the same ladder can be grabbed again, so holding Up does not snap you straight back on.
Step Off Ladder Sideways	When ticked, walking left or right lets go of the ladder.

Making a ladder climbable

1. Drag in a ladder prefab, or any sprite you like.
2. Add a **Box Collider 2D** and tick **Is Trigger**.
3. Set its **Tag** to .

That is all. The character will grab it when you press Up or Down while touching it.

Drag **Interactive Water** from **Prefabs/Extended Prefabs** into your scene. It is a working pool out of the box — it ripples when something falls in, floats wooden objects, sinks heavy ones, and warps the view when the character goes under.

Wooden things float, and the surface really moves

Go under and everything below the waterline ripples

Setting	In plain words
Width / Height	The size of the pool, in world units. Change these rather than scaling the object.
Bottom Width	Narrows the bottom edge so the water fits a V-shaped riverbed. Leave it at 1 for a square pool, lower it if the water pokes out through sloped banks.
Num Of Vertices	How finely the surface is divided. More gives smaller, finer ripples. Around 96 to 160 is plenty.
Spring Constant / Damping / Spread	The feel of the ripples: how springy they are, how fast they die away, and how far they travel.

The demo pool in the Scene view. Its bottom edge is tapered with Bottom Width so it follows the shape of the riverbed instead of poking through the banks

Making things float

Water works out what floats using **density**, exactly like real life. Anything lighter than the water floats, anything heavier sinks.

1. Add a **Pushable Prop** component to the object.
2. Set **Density** to about **0.5** for wood, or **2.2** for stone and metal.
3. Put the object on the **Pushable** layer.

Mass is worked out from the object's size automatically, so scaling a crate up in the scene really does make it heavier. You do not have to type in numbers.

Two small things that are easy to miss: keep the water **behind** your ground art (that is what hides the straight edges of the water rectangle), and make sure the water object sits on the **Water** layer so the character knows to start swimming.

Depth and parallax

Three layers of depth — black in front, mid grey behind it, pale grey furthest away

The demo camera is a **perspective** camera, not the usual flat 2D one. That means Unity gives you parallax for free — background layers drift more slowly than the ground simply because they sit further away.

The background is split into three groups under `ENVIRONMENT/Parallax`. Each sits at a different distance:

Layer	Distance	How much it drifts
Near	<code>0.45</code>	About 4%
Midground	<code>1.0</code>	About 9%
Far	<code>1.7</code>	About 15%

Want more or less depth? Move a whole layer group further away or closer along **Z**. There is no script to configure.

One catch worth knowing: pushing something further away also makes it look smaller, because that is how perspective works. If you move a layer back, scale it up a little to match.

Atmosphere

Particles

All the ambient effects live under `FX/Placed FX` in the demo scene, in three groups: **Falling Leaves**, **Dust Motes** and **Smoke Dark Soft**. They are placed around the level rather than following the camera, so you can add, move or delete individual emitters wherever you want them.

To add more, just drag a prefab from `Prefabs/Particles` into the scene and position it.

Post-processing

The look — the darkened corners, the glow around the lanterns, the fine grain — comes from a single post-processing profile at `Settings/Post Processing.asset`, applied by the **Post Processing** object in the scene.

Effect	What it adds
Vignette	Darkens the corners and draws the eye to the middle of the screen.
Bloom	Makes the bright sky bleed into the silhouettes, and lights up the lanterns.
Color Adjustments	A touch of extra contrast, so the black shapes stay crisp.
Film Grain	A fine texture that keeps the flat sky from looking lifeless.

Select the **Post Processing** object and tweak any of it live while the game runs.

Please leave HDR switched off in `Settings/UniversalRP.asset`. This pack is pure black and white, and with HDR turned on Unity's colour buffer gives the blue channel less precision than red and green — which slowly tints the soft smoke and fog a faint yellow. Bloom already works perfectly well without it.

Troubleshooting

▼ The character will not jump

Select the Player and check the **Ground Check** slot in the Inspector — it needs an empty child object placed at the character's feet. If it is empty, the character never counts as standing on anything.

Also check that **Ground Layers** does not include the **Player** layer, or the character detects itself as ground.

The Inspector will warn you about both of these automatically.

▼ The character will not climb a ladder

The ladder needs two things: a **Collider 2D** with **Is Trigger** ticked, and the **Ladder** tag. Check both, then press Up while standing on it.

▼ Crates will not move

The crate needs a **Pushable Prop** component and a **Rigidbody 2D**, and it must be on a layer that is ticked in the character's **Grab Layers**. The **Pushable** layer is set up for exactly this.

Remember you have to hold **E** while walking — bumping into a crate only nudges it.

▼ I can see the straight edges of the water

The water is a rectangle, so its edges show wherever your ground art does not cover them. Two fixes, and you will usually want both:

Keep the water drawing **behind** your ground, and use the **Bottom Width** setting to taper the bottom of the pool so it follows the shape of the riverbed.

▼ Everything is pink

Your project is not using URP. Go to **Edit** → **Project Settings** → **Graphics** and assign `Settings/UniversalRP.asset` from the pack folder.

▼ The greys look slightly warm or yellow

HDR has been switched on somewhere. Open `Settings/UniversalRP.asset` and untick **HDR**. See the note in the Atmosphere section above for why.

Support

Something not working, or an idea for the next update? I read everything.
